Peripheral Blood Stem Cell Collection
(with G-CSF)
What is a stem cell?
Most stem cells are found in the bone marrow. Bone marrow is soft, sponge-like material in the centre of our bones. Stem cells have the ability to grow into all other blood cell types; including red blood cells which carry oxygen, white blood cells which fight infection and platelets which stop bleeding.

What is a peripheral blood stem cell transplant?
A peripheral blood stem cell transplant is a multistep process which involves ‘mobilising’ stem cells from your bone marrow then ‘collecting’ these cells from your blood stream. The stem cells are returned back to you at a later date following high dose chemotherapy. Not everyone proceeds to the high dose chemotherapy and stem cell transplant. This will be explained by your doctor.

Why do I need a peripheral blood stem cell transplant?
Chemotherapy is the main treatment for many forms of cancer. The use of high dose chemotherapy has been shown to be a better way of treating your disease as it results in the maximum number of cancer cells killed. Doses of chemotherapy are normally limited due to the toxic effects on the bone marrow and blood counts. Peripheral blood stem cell transplant allows high doses of chemotherapy to be given safely.

What is stem cells mobilisation?
Normally a very small number of stem cells circulate in the blood stream. To assist in the collection of your stem cells, we need to stimulate (or mobilise) the bone marrow to produce more. This involves using a growth factor called G-CSF.

G-CSF is a special protein which occurs naturally in the body and controls the process by which the bone marrow makes new blood cells. In this case, giving G-CSF causes high numbers of stem cells to be ‘mobilised’ from the bone marrow into the peripheral blood stream.

When are the stem cells collected?
On the fifth day of G-CSF injections, your peripheral blood stem cells should be at an acceptable level to start collecting. You will be given an appointment at the centre, usually 7am, for a special blood test called a CD34 blood test. This test allows us to measure how many stem cells are circulating in your peripheral blood.

How is the stem cell collection performed?
Your stem cells are collected or ‘harvested’ using a machine called a blood cell separator or apheresis machine. The blood cell separator uses disposable sterile tubing, which is used only once. A registered nurse will be with you throughout your procedure.
The nurse will insert a drip into each of your arms. Blood is drawn from one arm into the machine. The machine separates the stem cells from the rest of your blood. The stem cells are collected by the machine. The rest of your blood is returned to you via the drip in your other arm. During the procedure, the machine is continuously drawing, separating and returning your blood.

How will I know if the veins in my arms are good enough for stem cell collection?
A few days before your stem cell collection, a registered nurse will check the veins in your arms to see if they are suitable for the procedure. If your veins are not suitable for stem cell collection, the Apheresis and Stem Cell Transplant Coordinator will make a booking in the X-Ray department, for you to have a special line called a ‘Vascath’ inserted. A Vascath is a temporary plastic tube which allows blood
to be taken and returned during the stem cell collection procedure.

How long will the stem cell collection take?
The stem cell collection takes three (3) to four (4) hours a day to complete and is usually performed on a day patient basis. It is important to wear comfortable clothing. You should eat and drink as normal before, during and after your stem cell collection. You may wish to read a book, watch TV or a DVD throughout the procedure. Visitors are welcome, but should be limited to one or two people.

How often will I need this procedure?
Stem cell collections are performed on consecutive days. On average it takes three (3) stem cell collection procedures to obtain enough stem cells for a transplant.

Is the stem cell collection procedure painful?
The stem cell collection procedure does not hurt. You may feel some discomfort when the drips are inserted into each arm. This discomfort usually passes in a couple of minutes. If you need a Vascath for the stem cell collection, you may experience some discomfort at the insertion site. Please contact your doctor if discomfort is not relieved by paracetamol.

Are there any side effects or problems that could occur?
Your doctor is responsible for the overall supervision of the procedure. However, a registered nurse will monitor you throughout the procedure and will provide assistance should you experience any difficulties. Possible side effects include the following:

- The blood cell separator removes only a small amount of blood at any time, but you may feel dizzy, light-headed or cold.
- The drug used to stop your blood from clotting during the procedure may cause you to experience tingling in your lips or fingers. You also notice a sour taste in your mouth or feel queasy.

If you experience any of the above side effects it is important you tell the nurse straight away as any problems can be easily treated.

How will I feel after the stem cell collection?
You may feel tired or lethargic after the procedure. We ask that you organise a relative or friend to drive you home afterwards. It is unlikely you will experience any problems following the procedure. However, if you feel unwell or experience any side effects you should contact your doctor or the centre immediately.

What happens to my stem cells after the collection is completed?
Each stem cell collection will be tested to determine the suitability and quantity of stem cells collected. The results will take three (3) to four (4) hours and will help determine how many collections are required to achieve sufficient stem cells for a transplant. The stem cells are then frozen in liquid nitrogen and then stored at The Wesley Clinic Research Centre Transplant Laboratory.

The stem cells collected may be given back to you at a later date following high dose chemotherapy in a manner similar to a blood transfusion.

How long are my stem cells stored for?
Stem cells are routinely stored for up to five (5) years. After five (5) years of storage the need for continued storage of your stem cells will be reviewed on a regular basis.

Will the costs be covered by my health fund?
Issues regarding costs will be discussed with you. Costs covered depend on your health fund, level of cover and your disease.

There is no cost for storing stem cells in the first three months. Storage charges will be in accordance with the agreement you sign prior to starting stem cell collection.

Storage of stem cell charges are not reimbursed by Medicare or your health fund.

Out of pocket costs may occur in the following areas:

- Pharmacy costs
- Insertion of Vascath
- Storage of stem cells.
